

Are datacenters that use more than 1 GW of power actually going to be built? Why do AI companies think that level of centralization is so advantageous?

Posted by u/Critical_Ad1355 • 0 points • 41 comments

From the energy perspective, it sounds like a nightmare trying to supply 1-2 GW of power reliably to one place. Especially if it's going to be clean energy around the clock.

Is it unrealistic optimism that data centers sucking up 1-2 GW of power are going to be built?

They should look in to what they are hosting influencer rubbish, keyboard warrior posts , a million and one selfies that nobody cares about the useless pointless social media apps that are designed to make you feel worthless...when these datacentrs run out of money as it cists a fortune or more likekly we all have power cuts as if were really going to electric cars ect in 5 years where is the infastracter...all the energy companies have pumped out millions to their shareholders thats why were buryng coal and oil still...people and influencers/instagramers will reevaluate their lives when they have noelectricity to power there devices, charge a over priced telsa or get on the inyernet we eont need data centres to store pointless rubbish of no use to no one

Full disclosure I'm far from an expert on data centers but I wouldn't believe everything you hear in the news. Lots of companies make bold claims about being 100% clean energy but when you read the fine print they purchase carbon offsets that were forested a long time ago in a land far, far away. I suspect somewhere in Indonesia are some very rich farmers with orangutan sanctuaries and palm oil plantations and also a thriving carbon offset business
