

AI servers as environmental threats

Posted by u/d1rtf4rm • • 0 points • 60 comments

So I've been seeing so so so many sensational instagram posts about the apparent catastrophic waste of water... (yes I'm also smart enough to know that social media isn't a reliable source of factual information.)

I'm not a complete Luddite, but as I age, it's getting worse.

I have built water cooled computers in the past.
I have tinkered with car engines and radiators...

At a consumer level, water cooling is essentially a self contained system.

I imagine that servers would be a scaled up version....

I did google this, and the main answer was the the loss of water was basically in the form of evaporation - which to my understanding is part of the water cycle, and steam will eventually, at some point return to its liquid state...

The secondary answer was a vague mention of water generated electricity, which again, to my knowledge, doesn't like eradicate water...

Further more, if it's in a contained system.. it doesn't need to be potable... why aren't we using our virtually endless supply of sea water if this is a problem...

I'm just sick of having an uninformed opinion, can someone please explain.
