

AI data centers are forcing dirty 'peaker' power plants back into service

Posted by u/EchoOfOppenheimer • 0 points • 4 comments

The AI boom is officially reversing the green energy transition. A new Reuters investigation reveals that skyrocketing electricity demand from data centers is forcing the U.S. grid to resurrect obsolete peaker power plants-inefficient, 1960s-era fossil fuel units that were scheduled for demolition. In places like Chicago's Pilsen neighborhood, these dirty facilities are being kept online to prevent blackouts, concentrating pollution in low-income communities just to keep the servers running.

That's disappointing.

Only a fool would call natural gas power plants dirty.

We want renewables to replace fossil fuels, but that's extremely difficult when growth in energy demand outpaces our ability to build renewables. Renewables require a ton of metals, and a full transition is [bottlenecked by mining](<https://news.umich.edu/copper-cant-be-mined-fast-enough-to-electrify-the-us/>) (mainly the permitting process, which is valid as the ecological impacts aren't minor).

Despite big growth in the renewables sector, we're burning [far more coal, oil, and natural gas] (<https://ourworldindata.org/grapher/global-energy-substitution>) than we were 5 years ago. As long as energy demand outpaces growth in renewable infrastructure, this will continue to be the case. A sustainable future requires changing our energy sources *and* lowering total energy consumption; AI isn't helping with either.

There's no solution to the climate crisis that doesn't involve pumping the brakes on unchecked growth.
